Introduction

Dynamic programming is a technique to solve problems by breaking it down into a colle ction of sub-problems, solving each of those sub-problems just once and storing these solutions inside the cache memory in case the same problem occurs the next time.

Dynamic Programming is mainly an optimization over plain recursion.

Wherever we see a recursive solution that has repeated calls for same inputs, we can o ptimize it using Dynamic Programming.

This simple optimization reduces the time complexities from exponential to polynomial.

There are two different ways to store our values so that they can be reused at a later instance. They are as follows:

- 1. Memoization or the Top Down Approach.
- 2. Tabulation or the Bottom Up approach.

In Memoization we start from the extreme state and compute result by using values th at can reach the destination state i.e the base state.

In Tabulation we start from the base state and then compute results all the way till the extreme state.

Note: To store the intermediate results we can use Array, Matrix, Hashmap etc., all we need is data storage and retrieval with a specific key.

How to find the use case of Dynamic Programming?

You can use DP if the problem can be,

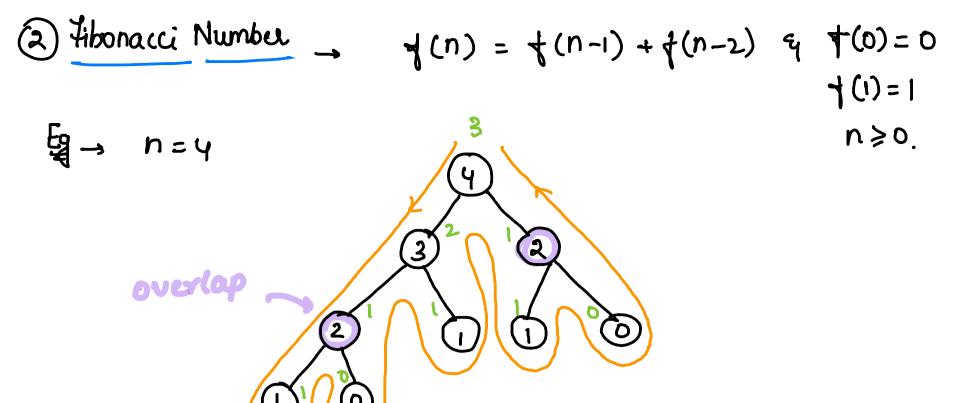

- 1. Divided into sub-problems
- 2. Solved using a recursive solution
- 3. Containing repetitive sub-problems

(1) Climbing Stails _, yours a value 'N', find the number of ways to heach N & jumps possible are ONG of two.

* Here we can see for (2), (3)

the supproblem is being done multiple time, we can solve using do.

```
class Solution {
    public:
        int totalWays(int currentStair, int targetStair, unordered_map<int,int> &memo){
            if(currentStair==targetStair){
                return 1;
            }
            if(currentStair > targetStair){
10
                return 0;
11
12
13
            int currentKey = currentStair;
14
            if(memo.find(currentKey)!=memo.end()){
15
16
                return memo[currentKey];
17
            }
18
19
            int oneStep = totalWays(currentStair+1, targetStair, memo);
20
            int twoStep = totalWays(currentStair+2, targetStair, memo);
21
22
            memo[currentKey] = oneStep+twoStep;
23
24
            return oneStep+twoStep;
25
        }
27
        int climbStairs(int n) {
29
            unordered_map<int,int> memo;
30
            return totalWays(0,n,memo);
31
        }
32
    };
```

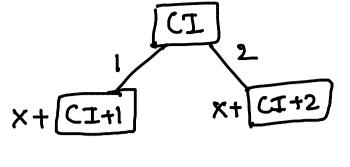

code_

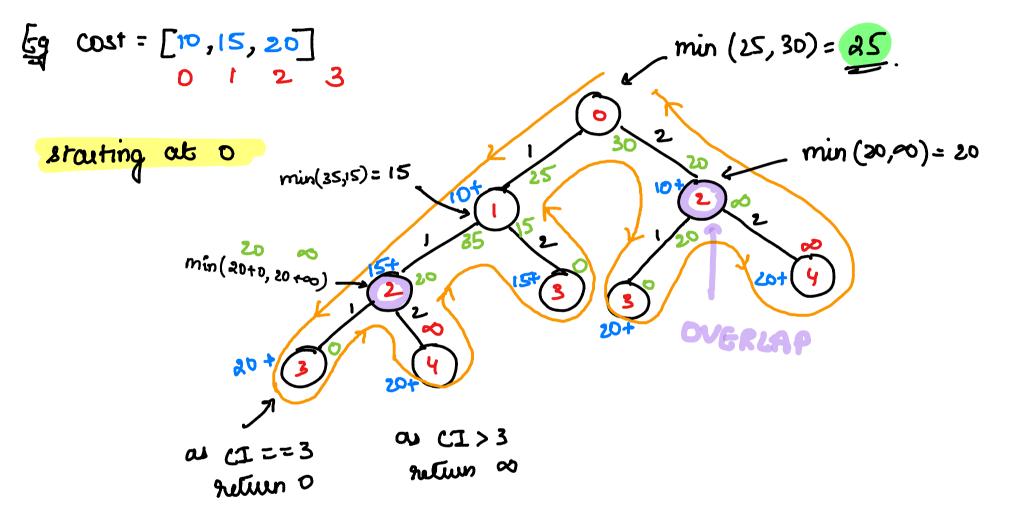

```
class Solution {
    public:
        int helper(int n, unordered_map<int,int>&memo){
            if(n<=1){
                 return n;
            int currentKey = n;
10
11
            if(memo.find(currentKey)!=memo.end()){
12
                return memo[currentKey];
13
            }
14
15
            int a = helper(n-1,memo);
17
            int b = helper(n-2,memo);
18
19
            memo[currentKey] = a+b;
            return memo[currentKey];
        }
22
23
        int fib(int n) {
24
25
            unordered_map<int,int>memo;
            return helper(n,memo);
27
        }
    };
```

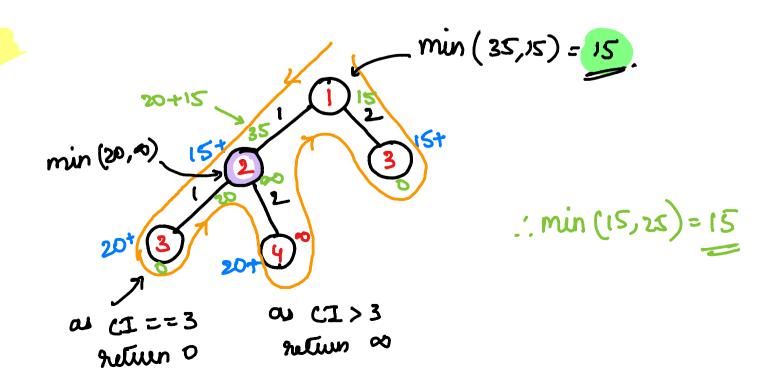

your costs away, find min cost to reach the end, starting from 0 or 1 4 making 1 or a jumps.

$$\therefore costs = \left[- \frac{x^{2}}{1} \right]$$

```
class Solution {
    public:
        int minCost(vector<int>&cost, int currentIndex, unordered_map<int,int> &m){
            if(currentIndex == cost.size()){
                return 0;
            }
10
            if(currentIndex > cost.size()){
                               // large values, serves as INFINITY
11
                return 1000;
12
            }
13
14
            if(m.find(currentIndex)!=m.end()){
15
                return m[currentIndex];
16
            }
17
            int oneJump = cost[currentIndex] + minCost(cost,currentIndex+1, m);
18
            int twoJump = cost[currentIndex] + minCost(cost,currentIndex+2, m);
19
20
            m[currentIndex] = min(oneJump, twoJump);
21
            return m[currentIndex];
22
        }
23
24
25
        int minCostClimbingStairs(vector<int>& cost) {
            unordered_map<int,int> m;
26
            return min( minCost(cost,0,m), minCost(cost,1,m));
27
28
        }
29 };
```

4 House Robber - given an away of no. suprementing money, find max amount, that can be robbed without choosing the adjacent house.

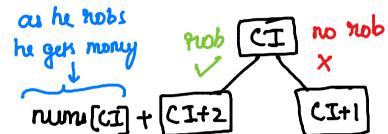

Eg nums =
$$[2,7,9,3,1]$$
 \Rightarrow max amount = $2+9+1=12$.

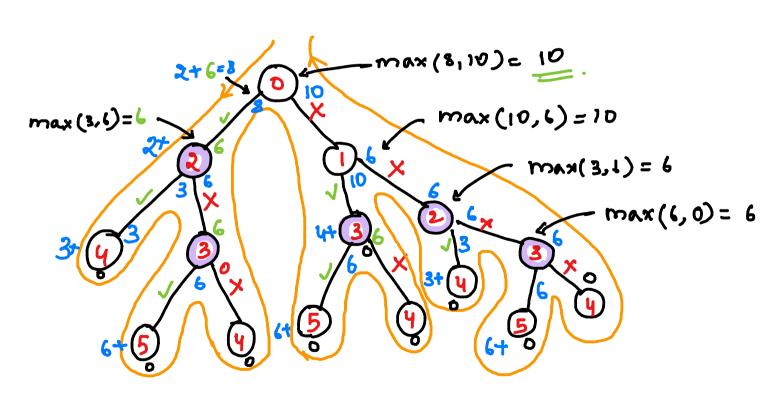

to avoid adjacut

to avoid adjacut

amount = nums[cI] & cI = cI+2

else cI = cI+1

as c1>3

if selected, else continue-

```
class Solution {
    public:
        int helper(vector<int>&nums, int currentIndex, unordered_map<int,int>&m){
            if(currentIndex >= nums.size()){
                return 0;
            }
10
            int currentKey = currentIndex;
11
12
            if(m.find(currentKey)!=m.end()){
13
                return m[currentKey];
14
            }
15
            int rob = nums[currentKey] + helper(nums, currentIndex+2, m);
            int noRob = helper(nums, currentIndex+1, m);
17
18
19
            m[currentIndex] = max(rob, noRob);
20
21
            return m[currentIndex];
22
        }
23
        int rob(vector<int>& nums) {
24
25
            unordered_map<int,int> m;
            return helper(nums,0,m);
26
27
        }
28 };
```

5 House Robber - II ->

In this problem, the approach will be similar to previous one, but the houses are in circle, which means that

- * if we start from 1st house, then we can't not the
- * if we start from 2nd house, then we can not the
- * and ruturn max value between 1st house & 2nd house * if only I house is present, then not it directly.

Code

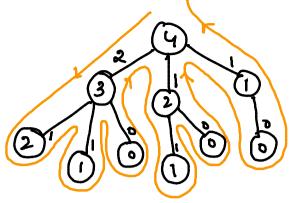

```
class Solution {
    public:
        int helper(vector<int>&nums, int currentIndex, int lastIndex, unordered_map<int,int>&m){
            if(currentIndex > lastIndex){
                return 0;
10
            int currentKey = currentIndex;
11
12
            if(m.find(currentKey)!=m.end()){
13
                return m[currentKey];
14
15
            int rob = nums[currentKey] + helper(nums, currentIndex+2, lastIndex, m);
17
            int noRob = helper(nums, currentIndex+1, lastIndex, m);
19
            m[currentIndex] = max(rob, noRob);
            return m[currentIndex];
        int rob(vector<int>& nums) {
            int n = nums.size();
            if(n==1)
                      return nums[0];
            unordered_map<int,int> memo1,memo2;
            // we can start robbing from 2 houses
            int firstHouse = helper(nums, 0, n-2, memo1);
            int secondHouse = helper(nums, 1, n-1, memo2);
            return max(firstHouse, secondHouse);
36 };
```

6 N-th Tribonacci -> given n, tind Tn

Tn+3 = Tn+Tn+1+Tn+2 & n>0 To=0, T1=1, T2=1.

Eg n=4

4 (2+1+1)

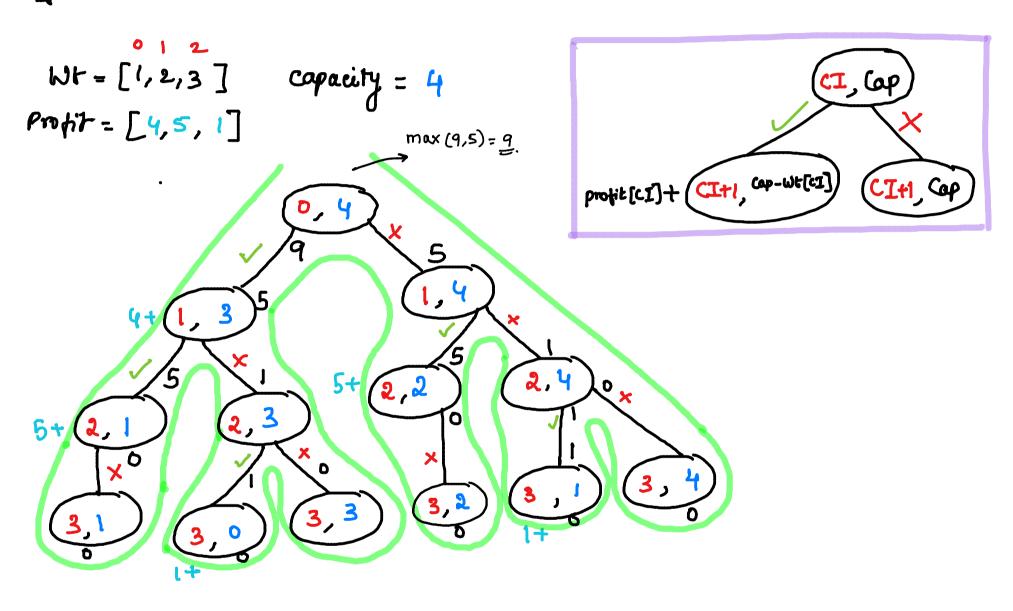

code

```
class Solution {
    public:
         int helper(int n, unordered_map<int,int> &m){
             if(n <= 1){
                 return n;
             }
             if(n==2){
10
                 return 1;
11
             }
12
13
             int currentNum = n;
14
15
             if(m.find(currentNum)!=m.end()){
16
                 return m[currentNum];
17
             }
18
19
             int a = helper(n-1,m);
20
             int b = helper(n-2,m);
21
             int c = helper(n-3,m);
22
23
             m[currentNum] = a+b+c;
24
25
             return m[currentNum];
26
        }
27
28
         int tribonacci(int n) {
29
             unordered_map<int,int>m;
30
             return helper(n,m);
31
        }
    };
32
```

$$7$$
 0-1 Knapsack Problem \rightarrow find max profit such that the weight of all items $\langle = \text{capacity} \rangle$.

Where $[3,4,4,5]$ \rightarrow if we release $[2,3,1,4]$ \rightarrow if we release $[3,3,1,4]$ \rightarrow if the total weight $[3,4,5]$ \rightarrow then total weight $[3,4,5]$ $= 3+5=8$.

Eg profit are 2+4=6. That max profit possible

in at every step,

if not selecting, in element CI by 1

```
class Solution
        public:
        int helper(int W, int wt[], int val[], int n, int curr,
                                     unordered_map<string,int> &memo){
            if(curr==n) return 0;
            // Instead of Matrix we can use strings as unique keys
10
            string currKey = to_string(curr)+"_"+to_string(W);
11
            if(memo.find(currKey)!=memo.end()) return memo[currKey];
12
13
14
            int currWt = wt[curr];
            int currVal = val[curr];
15
16
17
            int selected = 0;
18
            if(currWt<=W){</pre>
19
                selected = currVal + helper(W-currWt, wt, val, n, curr+1, memo);
20
            }
21
22
            int notSelected = helper(W, wt, val, n, curr+1, memo);
23
24
            memo[currKey] = max(selected, notSelected);
            return memo[currKey];
25
        }
26
27
28
29
        int knapSack(int W, int wt[], int val[], int n)
30
        {
31
           unordered_map<string,int> memo;
32
           return helper(W, wt, val, n, 0, memo);
33
34
    };
```

(8) Partition Equal Subset Sum

given an array, find if it can be divided into two subsets whose sum is equal.

. - initially kind sum of elements in allay.

- 1) if sum is odd then return False 2) if sum is even, then proceed.
- → spind a subset whose value == sum/2 which means that the other subset will have value == sum/2.

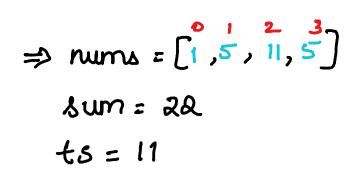

- lets say ts = sum/2 (ts is target sum)

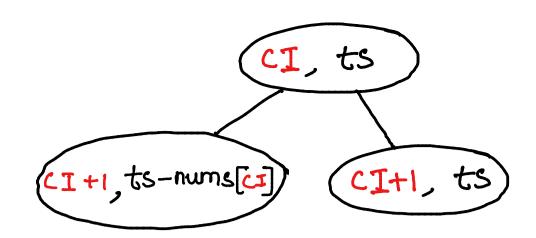

- At every index, we have 2 choices

[CI]

- 1) if we select then ts = ts-nums[CI]

 CI = CI+1
- 2) if we do not select then to = to (i.e remains cI=cI+1
- 3) return OR of left & right branch.

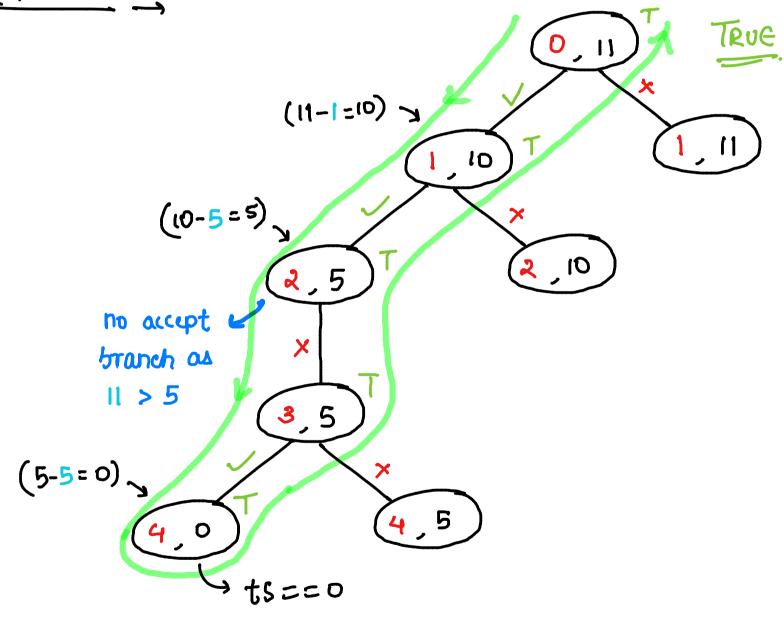

Here sum /2 ==0

i durding into 2 subsets is possible.

Explanation

> that subset is found
y return True

as we are using OR, one True branch is sufficient

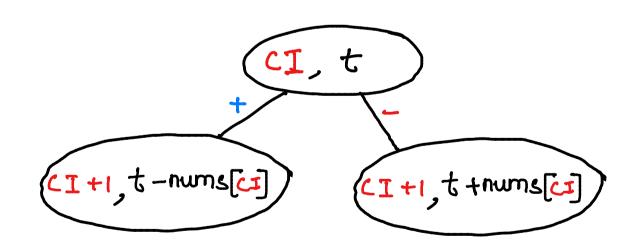

```
class Solution {
    public:
        bool isPossible(int targetSum,int currentIndex, vector<int>&nums,
                                         unordered_map<string, bool> &memo){
            if(targetSum == 0)
                return true;
            if(currentIndex >= nums.size())
11
                return false;
12
13
            string currentKey = to_string(currentIndex)+"_"+to_string(targetSum);
14
15
            if(memo.find(currentKey)!=memo.end()){
                return memo[currentKey];
17
19
            bool possible = false;
            if(nums[currentIndex]<=targetSum)</pre>
22
                possible = isPossible(targetSum-nums[currentIndex], currentIndex+1, nums, memo);
            // if already Possible then return True directly
24
25
            if(possible){
                memo[currentKey] = possible;
                return true;
            }
29
            bool notPossible = isPossible(targetSum, currentIndex+1, nums, memo);
32
            memo[currentKey] = possible||notPossible;
            return memo[currentKey];
34
        }
        bool canPartition(vector<int>& nums) {
36
            int total = 0;
            for(auto it:nums) total+= it;
            if(total%2!=0) return false;
42
            unordered_map<string, bool> memo;
44
            return isPossible(total/2,0, nums,memo);
        }
    };
```

given an away & target, find the number of ways to reach target by using t or - before each element in areay.

च्य

```
Input: nums = [1,1,1,1,1], target = 3
Output: 5
Explanation: There are 5 ways to assign symbols to make the sum of nums be target 3.
-1 + 1 + 1 + 1 + 1 = 3
+1 - 1 + 1 + 1 + 1 = 3
+1 + 1 - 1 + 1 + 1 = 3
+1 + 1 + 1 - 1 + 1 = 3
+1 + 1 + 1 + 1 - 1 = 3
```

 \rightarrow at every index are can use + or - sign if + then $t = t - (+ nums[cI]) \Rightarrow t - nums[cI]$ if - then $t = t - (-nums[cI]) \Rightarrow t + nums[cI]$

-> at every node, return the sum of values from left of right. Because we need to find the total number of ways.

```
class Solution {
    public:
        int totalWays(int currentIndex, vector<int>&nums, int target, unordered_map<string,int> &memo){
            if(target==0 and currentIndex==nums.size()){
                return 1;
            if(currentIndex>=nums.size() and target!=0){
                return 0;
11
12
13
            string key = to_string(currentIndex)+"_"+to_string(target);
            if(memo.find(key)!=memo.end()){
                return memo[key];
            int plus = totalWays(currentIndex+1, nums, target-nums[currentIndex],memo);
            int minus = totalWays(currentIndex+1, nums, target+nums[currentIndex],memo);
21
            memo[key] = plus+minus;
            return plus+minus;
        }
        int findTargetSumWays(vector<int>& nums, int target) {
            unordered_map<string,int> memo;
            return totalWays(0,nums,target,memo);
   };
```

© Count number of subtets with given difference →

This is similar to Target Sum.

given the difference between two subsets, and an away find no. of subsets with the difference.

Approach

Let say SI - SZ = difference (given) — (1)we can calculate sum of every element, say sum

4 it can be said that for 2 subset SI = ISZ SI + SZ = Sum . (2)

Now 0+2 $\Rightarrow 2(81) = difference + sum$ 81 = (difference + sum)/2.

-s Amplement Target soum with target value = &1

(1) Delite and Earn

You are given an integer array nums. You want to maximize the number of points you get by performing the following operation any number of times:

Pick any nums[i] and delete it to earn nums[i] points. Afterwards, you must delete every element equal to nums[i] - 1 and every element equal to nums[i] + 1.

Return the **maximum number of points** you can earn by applying the above operation some number of times.

$$E_{g}$$
 rum = [2,2,3,3,3,4]

→ if we start dulching 2, then result = 2+2 = 4

then numer = [2 2 3 3 4]

then nums = [3,3,3,4]

4 we need to delete all 2+1 & 2-1 => numi = [4]

→ if we delete 4, then result = 4+4 = 3.

q rums = []

(07)

→ if we start deleting 3, then result = 3+3+3 = 9.

then rums = [2,2,4]

4 we nud to delete all 3-1 € 3+1 ⇒ nums = []

: rusult = 9.

(or)

- 4 we start deleting 4, then result = 4

then nums = [2,2,3,3,3]

4 we need to delete all 4+1 & 4-1 => nume = [2,2]

- if we delete 2 then result = 4+4 = 3.

& rums = []

we can store frequency of each element and use the similar approach

num =
$$[2, 2, 3, 3, 3, 4]$$
 fuq = $\begin{bmatrix} 0 & 2 & 3 & 1 \\ & 1 & 2 & 3 & 4 \end{bmatrix}$

CI * fuq (CI) + CI+2 (CI+1)

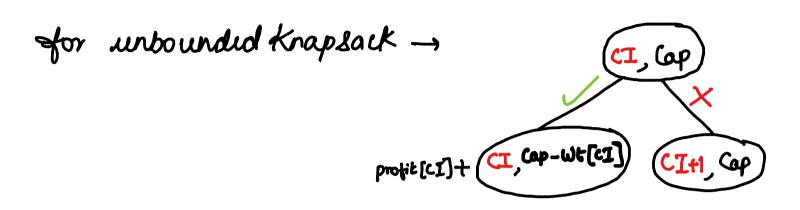

code

```
class Solution {
    public:
        int maxPoints(vector<int>& freq, int currentIndex, unordered_map<int,int>&memo){
            if(currentIndex >= freq.size()) return 0;
            int key = currentIndex;
            if(memo.find(key) != memo.end()) return memo[key];
            int Delete = currentIndex*freq[currentIndex] + maxPoints(freq, currentIndex+2, memo);
12
            int NotDelete = maxPoints(freq, currentIndex+1, memo);
            memo[key] = max(Delete, NotDelete);
17
            return memo[key];
        int deleteAndEarn(vector<int>& nums) {
            int maxi = *max_element(nums.begin(), nums.end());
            vector<int> freq(maxi+1, 0);
            for(auto i: nums) freq[i]++;
            unordered_map<int,int> memo;
            return maxPoints(freq, 0, memo);
   };
```

Unbounded knapsack _ similar to 0-1 knapsack but allows _ us to choose an item more than once

Eg $wt = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$ values = $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$ capacity = 3

if bounded knapsack then profit = 2. (2,1)
if unbounded knapsack then profit = 3. (1,1,1)

code

```

            vector<vector<int>> memo( N , vector<int> (W+1, -1));
27
            return helper(W, wt, val, N, 0, memo);
    };
```

(Similar to unbounded knapsack)

liven an away of coins & amount, find total number of ways) combinations to make up that amount.

Eg coins =
$$[1,2,5]$$

amount = $[1,2,5]$

coins = $[-x]$

code__

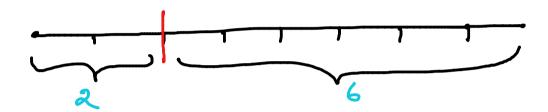

```
class Solution {
    public:
        int totalWays(int currentIndex, vector<int>& coins, int amount, vector<vector<int>>&memo){
            if(amount == 0) return 1; // amount==0 means that target is reached so return 1
            if(currentIndex >= coins.size()) return 0; //if index is out of bounds then return 0
            if(memo[currentIndex][amount]!=-1) return memo[currentIndex][amount];
            int consider = 0;
11
            if(coins[currentIndex]<=amount){</pre>
12
                consider = totalWays(currentIndex,coins,amount-coins[currentIndex],memo);
13
14
            int notConsider = totalWays(currentIndex+1,coins,amount,memo);
15
16
            memo[currentIndex][amount] = consider+notConsider;
            return memo[currentIndex][amount];
17
18
19
        int change(int amount, vector<int>& coins) {
21
            vector<vector<int>>memo(coins.size()+1,vector<int>(amount+1,-1));
            return totalWays(0,coins,amount,memo);
22
23
24
    };
```

```
class Solution {
    public:
        int minimumCoins(int currentIndex, vector<int>& coins, int amount, vector<vector<int>>&memo){
            if(amount == 0)
                             return 0;
            if(currentIndex >= coins.size())
                                              return 100000; //Any Max Value outside boundary
            if(memo[currentIndex][amount]!=-1) return memo[currentIndex][amount];
            int consider = 100000;
            if(coins[currentIndex]<=amount){</pre>
11
                consider = 1 + minimumCoins(currentIndex, coins, amount-coins[currentIndex], memo);
14
            int notConsider = minimumCoins(currentIndex+1, coins, amount, memo);
            memo[currentIndex][amount]= min(consider,notConsider);
            return memo[currentIndex][amount];
        }
        int coinChange(vector<int>& coins, int amount) {
            vector<vector<int>>memo(coins.size()+1,vector<int>(amount+1,-1));
24
            int ans = minimumCoins(0, coins, amount, memo);
            return (ans==100000)? -1 : ans;
        }
   };
```

given a tool of length N and curay of price find the max value that can be obtained by cutting rood.

Eg
$$N=8$$
 prices = $\begin{bmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 1 & 5 & 8 & 9 & 10 & 17 & 17 & 20 \end{bmatrix}$

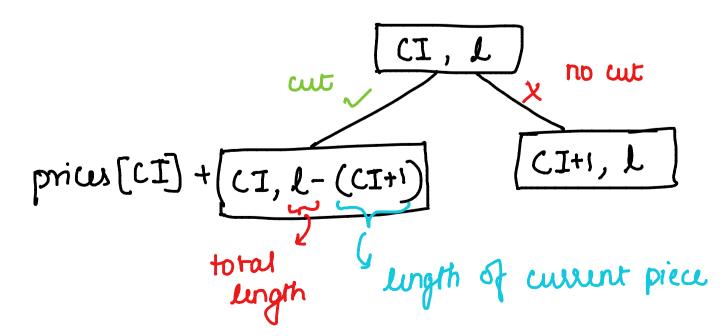

* price of a spiece is prices [CI], whose length is CI+1

if we cut our rod into 2 pieces of length 2,6 we get max value of 5+17 is $\frac{22}{2}$.

- there night be other ways, but this particular configuration returns more value

* At any instance length of current piece is CI+1

```
class Solution{
      public:
        int maxProfit(int price[],int currentIndex, int n, vector<vector<int>>&memo){
            if(n==0) return 0;
            if(currentIndex>=n) return 0;
            if(memo[currentIndex][n]!=-1) return memo[currentIndex][n];
            int selected = 0;
11
            if(currentIndex+1<=n){</pre>
                selected = price[currentIndex]+maxProfit(price, currentIndex, n-(currentIndex+1), memo);
12
            }
            int notSelected = maxProfit(price, currentIndex+1, n, memo);
14
15
            memo[currentIndex][n] = max(selected, notSelected);
            return memo[currentIndex][n];
17
        int cutRod(int price[], int n) {
            vector<vector<int>> memo(n+1, vector<int>(n+1,-1));
            return maxProfit(price,0,n,memo);
21
23 };
```
